

# Fourier decomposition of variable stars using regularized regression

Daniel Wysocki

Rochester Institute of Technology

AST Graduate Seminar – December 7th, 2015

# Variable Stars

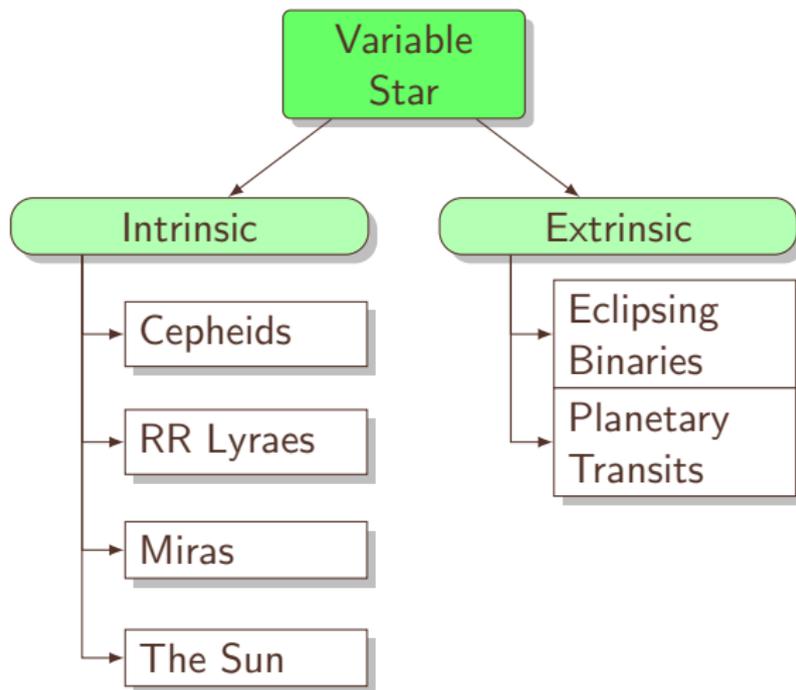

# Overview

- in general, any star whose brightness changes on short timescales is a variable star
- many different types exist

# Some classes of variable stars

# Pulsating periodic intrinsic variables

For the remainder of this talk:

variable star  $\equiv$  pulsating periodic intrinsic variable star.

- not in hydrostatic equilibrium
  - typically in the instability strip
- periodic oscillation
  - predictable
- stellar pulsation
  - $\kappa$ -mechanism

# Henrietta Swan Leavitt

Public domain in USA

- worked as a “computer” at Harvard in the early 20th century
- discovered a relation between the period and luminosity of Cepheids
  - Leavitt’s law
  - standard candles
- enabled Edwin Hubble to measure the expansion of the Universe

Henrietta Swan Leavitt

# Light Curves

# Overview

- repeated photometric measurements of an object over time
- plotting brightness versus time gives us a light curve

# Light Curve of a Cepheid variable star

Visualization of OGLE-LMC-CEP-0002

# Fourier decomposition

Public domain in USA

Joseph Fourier

- any continuous, periodic function can be represented as an infinite Fourier series

$$f(t) = A_0 + \sum_{k=1}^{\infty} A_k \cos(k\omega t + \Phi_k)$$

- characterized by the angular frequency  $\omega$ , the mean  $A_0$ , the amplitudes  $A_k$ , and the phase shifts  $\Phi_k$

Fourier (1808)

# Fourier decomposition of periodic light curves

$$m(t) = A_0 + \sum_{k=1}^n A_k \cos(k\omega t + \Phi_k)$$

- Cepheid-like light curves well described by  $n$ th order Fourier Series
- physically they are close to harmonic oscillators

# Solving for series parameters

$$\begin{aligned}m(t) &= A_0 + \sum_{k=1}^n A_k \cos(k\omega t + \Phi_k) \\ &= A_0 + \sum_{k=1}^n [a_k \sin(k\omega t) + b_k \cos(k\omega t)]\end{aligned}$$

- Fourier series are non-linear
- simultaneously finding the optimal  $n$ ,  $\omega$ ,  $A_k$ , and  $\Phi_k$  is not easy

# Period finding

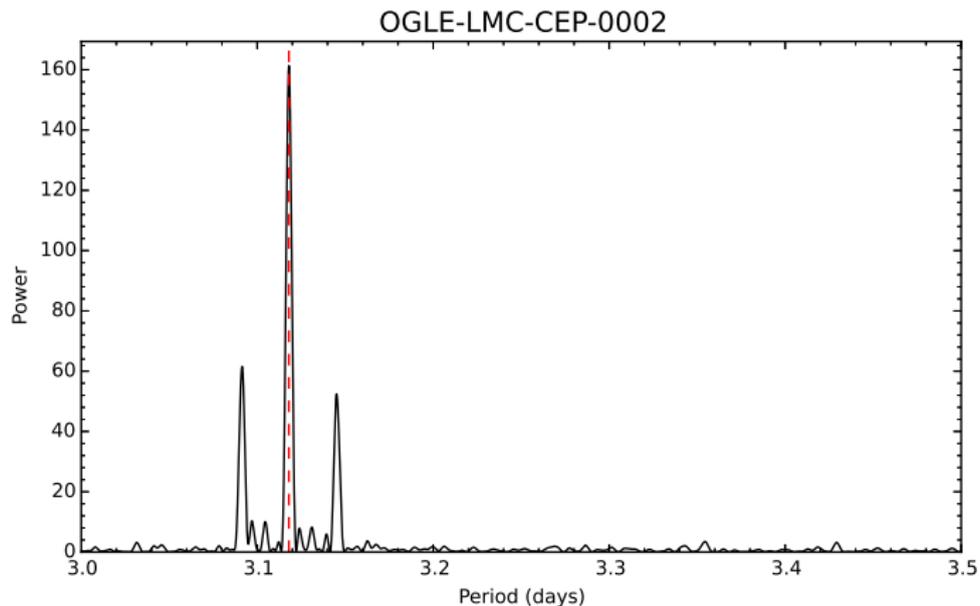

- the most important parameter is the period

$$\omega = 2\pi/P$$

- we can approximate this by itself using a periodogram
  - Lomb-Scargle

# Lomb-Scargle periodogram

Periodogram of star with 3.11804 day period

It's linear!

$$m(t) = A_0 + \sum_{k=1}^n [a_k \sin(k\omega t) + b_k \cos(k\omega t)]$$

can be written in the form

$$\mathbf{X}\vec{\beta} = \vec{y}$$

which can be approximated using ordinary linear regression

## System of equations

$$\vec{y} \rightarrow (m_1 \quad m_2 \quad \dots \quad m_N)$$

$$\vec{\beta} \rightarrow (A_0 \quad a_1 \quad b_1 \quad \dots \quad a_n \quad b_n)$$

$$\mathbf{X} \rightarrow \begin{pmatrix} 1 & \sin(1\omega t_1) & \cos(1\omega t_1) & \dots & \sin(n\omega t_1) & \cos(n\omega t_1) \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 1 & \sin(1\omega t_N) & \cos(1\omega t_N) & \dots & \sin(n\omega t_N) & \cos(n\omega t_N) \end{pmatrix}$$

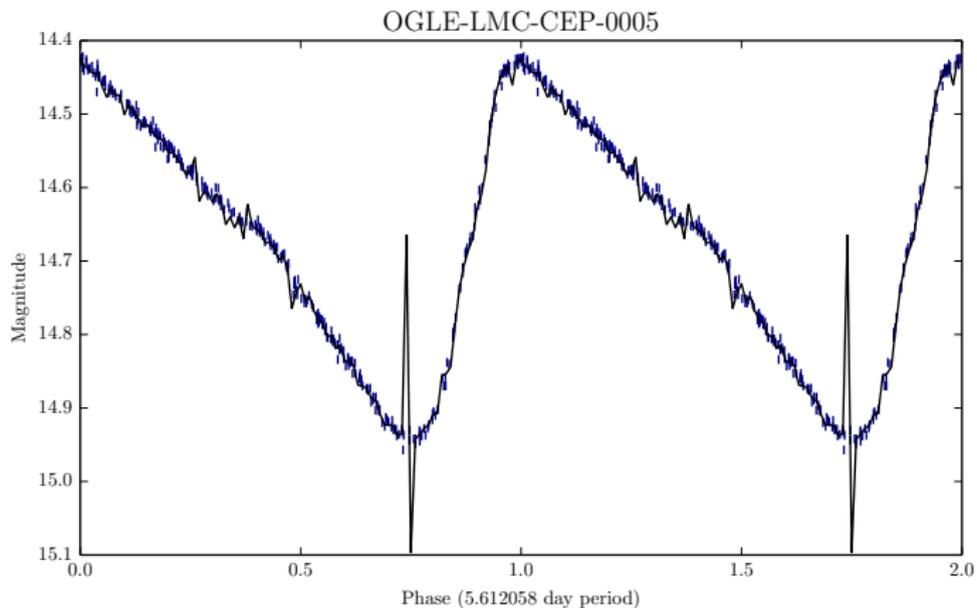

# How many terms?

- wait, we never decided on the order of the fit,  $n$
- it's just a truncated series expansion
  - more terms means better, right?
  - let's try 100 terms...

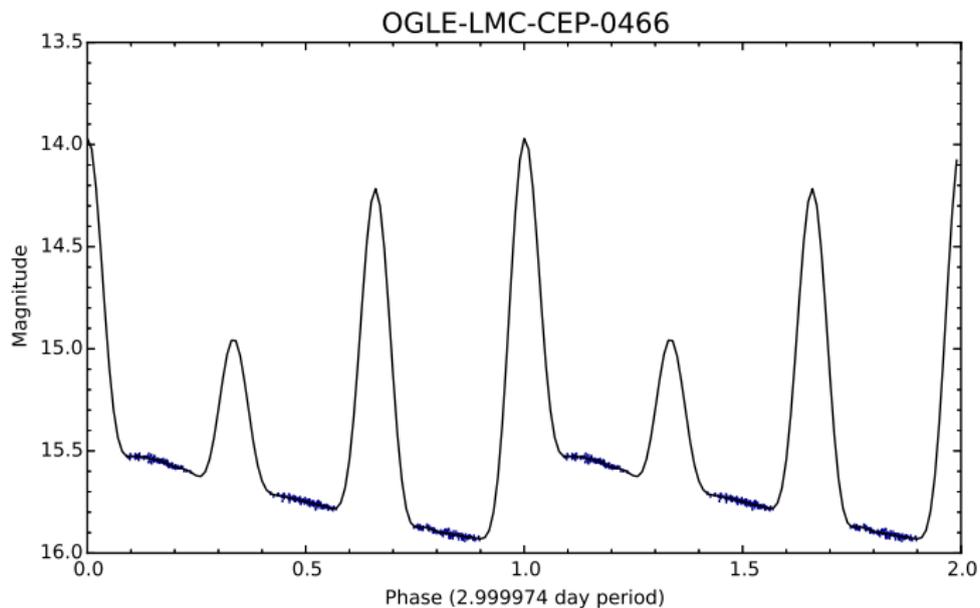

# Overfitting

100th order fit

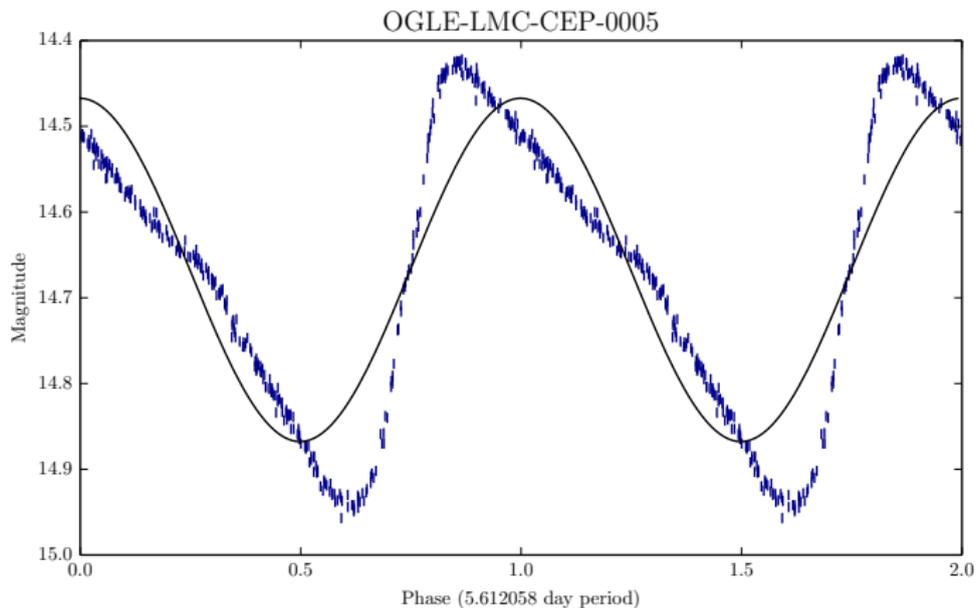

# Overfitting (again)

12th order fit

# Underfitting

1st order fit

# Choosing $n$

- need some criteria to decide the order of the fit
- Baart's criteria is often used for this
  - iterative approach, increasing  $n$  until diminishing returns
  - good at avoiding underfitting
  - bad at avoiding overfitting

# Taking a step back

- take photometric measurements
- find the period
- approximate coefficients with OLS
- find the best order of fit using Baart's criteria

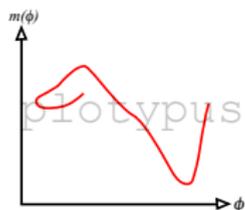

# Taking a step back

- take photometric measurements
- **periodogram**
- **regression**
- **model selection**

# Plotypus

- tool for modeling and plotting light curves
- free and open source
- version controlled and documented
- generated the light curve plots in this presentation
- [astrowego.github.io/plotypus/](https://astrowego.github.io/plotypus/)
- download today!

Bellinger, Wysocki, and Kanbur (2015b)

# Unconstrained regression

$$\mathbf{X}\vec{\beta} = \vec{y}$$

$$\begin{aligned} (A_0, a_k, b_k) &= \operatorname{argmin}_{\beta} \left\| \mathbf{X}\vec{\beta} - \vec{y} \right\|_2^2 \\ &= \operatorname{argmin}_{(A_0, a_k, b_k)} \sum_{i=1}^N \left( A_0 + \sum_{k=1}^n \begin{bmatrix} a_k \sin(k\omega t_i) \\ +b_k \cos(k\omega t_i) \end{bmatrix} - m_i \right)^2 \end{aligned}$$

Find coefficients which minimize magnitude of residual vector

$\ell_0$  regularization

$$(A_0, a_k, b_k) = \underset{\beta}{\operatorname{argmin}} \left\{ \left\| \mathbf{X}\vec{\beta} - \vec{y} \right\|_2^2 + \lambda \left\| \vec{\beta} \right\|_0 \right\}$$

- $\left\| \vec{\beta} \right\|_0$  is equal to the number of non-zero terms in  $\vec{\beta}$
- adds a penalty on the number of parameters, weighted by  $\lambda$
- this is computationally expensive

$\ell_1$  regularization (LASSO)

$$\begin{aligned}
 (A_0, a_k, b_k) &= \underset{\beta}{\operatorname{argmin}} \left\{ \left\| \mathbf{X}\vec{\beta} - \vec{y} \right\|_2^2 + \left\| \vec{\beta} \right\|_1 \right\} \\
 &= \underset{(A_0, a_k, b_k)}{\operatorname{argmin}} \left\{ \begin{aligned} &\sum_{i=1}^N \left( A_0 + \sum_{k=1}^n \begin{bmatrix} a_k \sin(k\omega t_i) \\ + b_k \cos(k\omega t_i) \end{bmatrix} - m_i \right)^2 \\ &+ \lambda \sum_{k=0}^n (|a_k| + |b_k|) \end{aligned} \right\}
 \end{aligned}$$

- least absolute shrinkage and selection operator (LASSO)
- adds a penalty on the sum of the amplitudes, weighted by  $\lambda$
- automatically zeroes out non-contributing terms

# Model selection with grid search

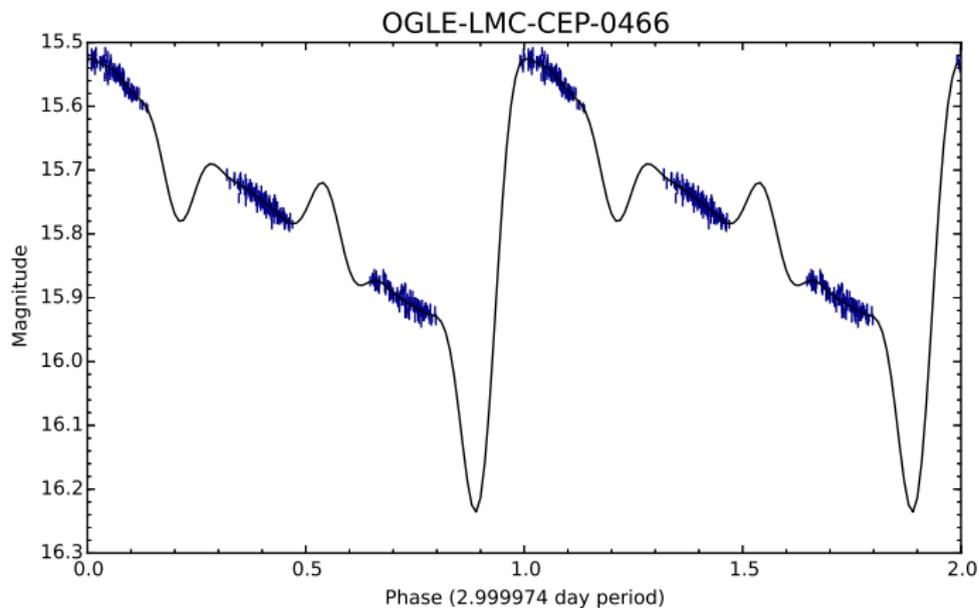

- use grid search with cross-validation
  - search over the order of fit  $n$
- cross-validation helps fit underlying function, not just the data

# Results

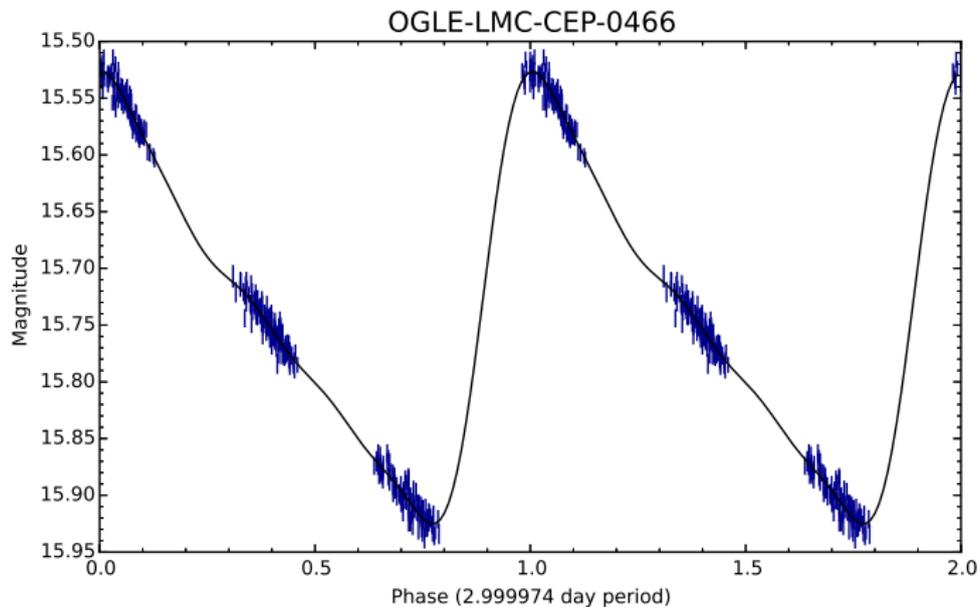

## OLS/Baart light curve

10th order fit using OLS/Baart.

# LASSO light curve

10th order fit using Lasso/Grid Search.

## Performance of LASSO/grid search versus OLS/Baart

Median coefficients of determination ( $R^2$ ) and median absolute deviations (MAD) for models selected by cross-validated LASSO and Baart's ordinary least squares on OGLE *I*-band photometry. P-values obtained by paired Mann-Whitney *U* tests.

# Missing harmonics

- LASSO makes no distinction between higher and lower order terms
  - if it doesn't contribute, it goes to zero
- this can result in  $A_i = 0$ , when  $A_j \neq 0$ ,  $j > i$ 
  - contrary to pulsation models, which say amplitude decreases with order

$$A_1 > A_2 > \dots > A_n$$

- explanations:
  - harmonics absent from observations
    - e.g. we observe only near zero-crossing
  - interference pattern in pulsation (gets political)
  - others? (please tell me)

# Multifrequency variable stars

$$m(t) = A_0 + \sum_{k_1=-n}^n \dots \sum_{k_p=-n}^n A_{\mathbf{k}} \cos((\mathbf{k} \cdot \boldsymbol{\omega})t + \Phi_{\mathbf{k}})$$

$$\mathbf{k} \rightarrow (k_1 \quad \dots \quad k_p) \quad \boldsymbol{\omega} \rightarrow (\omega_1 \quad \dots \quad \omega_p)$$

- some variable stars oscillate with multiple ( $p$ ) periods
- OLS fails to accurately fit these light curves
  - tools exist to manually fix certain amplitudes to zero
- LASSO successful in automatically zeroing out amplitudes
